Dimensionality Reduction Techniques

1. SVD)

- Using Numpy
 - Re-construct main dataset

2. Truncated SVD

- Using Sklearn
 - Re-construct main dataset)

3. SVDS

- Using Scipy
 - Re-construct main dataset)

4. Matrix Free Solvers

• Sparse Matrix & Pandas DF performance comparison

5. SVD on Breast Cancer Dataset

- Lets run some models
 - Perceptron
 - Logistic Regression
 - K-Nearest Neighbors

```
import os
In [1]:
         import sys
         import logging
         logging.basicConfig(filename="SA1_SVD.log",
                             filemode='w',
                             level=logging.INFO,
                             format="%(asctime)s : %(levelname)s : %(message)s")
         try:
             logging.info("#### Packages import ####")
             import numpy as np
             import pandas as pd
             import matplotlib.pyplot as plt
             import seaborn as sns
             import sklearn
             from sklearn import datasets
             import scipy
         except ImportError as ie:
             # Output expected ImportErrors
             logging.error(msg=ie.__class__.__name__ + " :: Missing Package --> " + ie.name)
         except Exception as exception:
             # Output unexpected Exceptions
             logging.info("#### Exceptions other than ModuleImportError ####")
```

```
logging.log(msg=(exception, False))
logging.log(msg=exception.__class__.__name__ + " :: " + exception.name)

%matplotlib inline
```

SVD-(Singular_Value_Decomposition)

Lets first understand how SVD works using a dummy dataset, then we will apply the same concept on Breast Cancer Dataset. There are multiple ways by which we can apply SVD on our dataset. First, I'll demonstrate the same using Numpy then via Sklearn.

Using--Numpy

```
X = pd.DataFrame({'col1':[9,4,7,4],
In [2]:
                              'col2':[3,2,1,2]})
In [3]:
Out[3]:
            col1 col2
         0
              9
                    3
         1
              4
                    2
         2
              7
                    1
         3
                    2
              4
In [4]:
          X.shape, X.ndim
Out[4]:
         ((4, 2), 2)
          from numpy.linalg import svd
In [5]:
          U,S,VT = svd(X,full_matrices=True,compute_uv=True,hermitian=False)
In [6]:
          pd.DataFrame(U)
In [7]:
Out[7]:
                             1
                                       2
                                                3
         0 -0.711633 -0.113179 -0.642945
                                         -0.259597
            -0.331229
                      -0.466058
                                0.650505
                                          -0.499920
                                0.385767
           -0.523597
                      0.743485
                                          0.155758
         3 -0.331229 -0.466058
                                0.121029
                                          0.811436
In [8]:
          Sigma = np.zeros((X.shape[0],X.shape[1]))
          Sigma
Out[8]: array([[0., 0.],
                 [0., 0.],
                 [0., 0.],
                 [0., 0.]])
In [9]:
          Sigma[:X.shape[1],:X.shape[1]] = np.diag(S)
          Sigma
```

Re-construct

How to re-construct the main dataset from U, Sigma and VT?

Way-1: Using Dot Product

Way-2: Using Matrix Multiplication

Truncated_SVD

Contrary to PCA, this estimator does not center the data before computing the singular value decomposition. This means it can work with sparse matrices efficiently.

In particular, truncated SVD works on term count/tf-idf matrices as returned by the vectorizers in :mod: sklearn.feature_extraction.text. In that context, it is known as latent semantic analysis (LSA).

This estimator supports two algorithms: a fast randomized SVD solver, and a "naive" algorithm that uses ARPACK as an eigensolver on X * X.T or X.T * X, whichever is more efficient.

Using--Sklearn

```
In [12]: from sklearn.decomposition import TruncatedSVD
In [13]: tsvd = TruncatedSVD(n_components=2)
```

```
X2 = pd.DataFrame(\{'col1':[9,4,7,4],
In [14]:
                             'col2':[3,2,1,2],
                             'col3':[5,6,7,1]})
         X2.shape, X2.ndim
In [15]:
Out[15]: ((4, 3), 2)
         X_transf = tsvd.fit_transform(X2)
In [16]:
        Variance of every component
          vect_magnitude = tsvd.explained_variance_
                                                              ## The magnitude or amount of v
In [17]:
          vect magnitude
Out[17]: array([6.42468871, 3.2616684])
         Here, explained variance represents the variance of both the components.
         np.var(X_transf[:,0]), np.var(X_transf[:,1])
In [18]:
Out[18]: (6.424688713036935, 3.261668395175186)
        Percentage of variations explained by components
          expln_var_ratio = tsvd.explained_variance_ratio_
In [19]:
                                                            ## Percentage of variation expl
          expln_var_ratio
Out[19]: array([0.63064429, 0.32016377])
         Here, explained_variance_ratio is the ratio of the variances in the
        components and the sum of the variance in the original dataset.
         np.var(X_transf,axis=0)/np.sum(np.var(X2,axis=0))
In [20]:
Out[20]: array([0.63064429, 0.32016377])
        Total percentage of variations explained by components
         tot_var_expln = np.sum((expln_var_ratio))*100
In [21]:
                                                             ## Total variation explained by
          print('Total variation explained by the components is {0:.3f}%'.format(tot_var_expln
         Total variation explained by the components is 95.081%
         It is just the addition of components individual percentage of variances.
         np.sum(np.var(X_transf,axis=0)/np.sum(np.var(X2,axis=0)))
In [22]:
Out[22]: 0.9508080597018034
        Number of components
         tsvd.n_components
                                      ## Number of generated components
In [23]:
Out[23]: 2
In [24]:
          VT x2 = tsvd.components
                                      ## These are the values of VT's i.e. the EIGEN VECTORS
          VT x2
```

localhost:8888/lab#Using--Scipy

```
Out[24]: array([[ 0.75687368, 0.23209938, 0.61095999], [ 0.53103415, 0.32653333, -0.7819071 ]])
```

So, one thing to understand here is that the above VT_x2 is representing the two eigen vectors whose amount of variation or magnitude(means the eigen value) is represented by singularvalues.

Here, one point to understand is that SVD is nothing but breaking the higher rank dataset into one set(U,Singma and VT) of Rank-1 matrices or closest approximation of main dataset is achieved by the addition of more than one set(U,Sigma and VT) of Rank-1 matrices which can yield a higher rank dataset.

Fittransform returns the product of U and Sigma, so if we want to reconstruct our main dataset then we just need to peform its matrix multiplication with the VT's or components.

```
Re-construct(TSVD)
```

How to re-construct the main dataset from U, Sigma and VT?

Way-1: Using Matrix Multiplication

Way-2: Using Dot Product

```
In [28]: pd.DataFrame(np.dot(U_Sigma_x2, VT_x2)).apply(lambda val : np.round(val,4))
```

	0	1	2
0	8.9769	3.0555	5.0075
1	4.4008	1.0362	5.8697
2	6.6635	1.8094	7.1094
3	4.1648	1.6038	0.9464

We have reterieved X2 that was our dataset of shape (4,3) with 12 elements and it is the closest approximate with two components having 8 elements.

Here, it might feels like we have saved a very little space but imagine if we have 1000 x 1000 dataset then in such as case we will only consume space of 2000 elements instead of 10,00,000.

SVDS

It is SVD for sparse matirces. It computes the largest or smallest k singular values/vectors for a sparse matrix. The order of the singular values is not guaranteed. It can use the following Eigen Value solvers:

- ARPACK(Stands for ARNoldi Package)
- LOBPCG(Stand for Locally Optimal Block Preconditioned Conjugate Gradient)

Using--Scipy

```
In [33]: | U_svds_x3, Sigma_svds_x3, VT_svds_x3 = svds(A=X3,k=2,solver='lobpcg')
In [34]:
          U_svds_x3
                             , 0.91381155],
Out[34]: array([[0.
                             , 0.
                                          ],
                 [0.30945484, 0.
                 [0.
                             , 0.40613847],
                             , 0.
                 [0.
                 [0.

         Re-Constructing Sparse Matrix from Pandas DataFrame
In [65]:
          X_sp_mat_recons = scipy.sparse.csr_matrix(X_sp_mat_df)
          X_sp_mat_recons.indptr.nbytes + X_sp_mat_recons.indptr.nbytes + X_sp_mat_recons.indice
In [66]:
         488004
Out[66]:
          ## Size of whole object(size of stored data + overhead)
In [67]:
          print("Size of re-constructed Sparse Matrix (size of stored data + overhead) is {} b
          Size of re-constructed Sparse Matrix (size of stored data + overhead) is 56 bytes
```

Here, we found that Sparse objects requires less storage space or memory, however, if we store the same data in the pandas

dataframe object then its storage becomes inefficient in terms of space consumption.

Execution_time_diff

Difference in execution time of SVDS on Sparse Matrix and Pandas DataFrame

```
In [68]: %timeit scipy.sparse.linalg.svds(X_sp_mat,k=200)
3.32 s ± 427 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)
In [69]: %timeit scipy.sparse.linalg.svds(X_sp_mat_df,k=200)
12.8 s ± 1.52 s per loop (mean ± std. dev. of 7 runs, 1 loop each)
```

For 200 largest singular values, time consumption with the dataframe object is more than double as compared to the Sparse object.

This is a copy of UCI ML Breast Cancer Wisconsin (Diagnostic) datasets. https://goo.gl/U2Uwz2

Features are computed from a digitized image of a fine needle aspirate (FNA) of a breast mass. They describe characteristics of the cell nuclei present in the image.

Separating plane described above was obtained using Multisurface Method-Tree (MSM-T) [K. P. Bennett, "Decision Tree Construction Via Linear Programming." Proceedings of the 4th Midwest Artificial Intelligence and Cognitive Science Society, pp. 97-101, 1992], a classification method which uses linear programming to construct a decision tree. Relevant features were selected using an exhaustive search in the space of 1-4 features and 1-3 separating planes.

The actual linear program used to obtain the separating plane in the 3-dimensional space is that described in: [K. P. Bennett and O. L. Mangasarian: "Robust Linear Programming Discrimination of Two Linearly Inseparable Sets", Optimization Methods and Software 1, 1992, 23-34].

This database is also available through the UW CS ftp server:

ftp ftp.cs.wisc.edu cd math-prog/cpo-dataset/machine-learn/WDBC/

Out[86]:
In [203...
           with plt.style.context('seaborn-poster'):
                sns.pairplot(data=cancer_transf[['PC1','PC2','PC3','Label']],hue='Label',height=
```

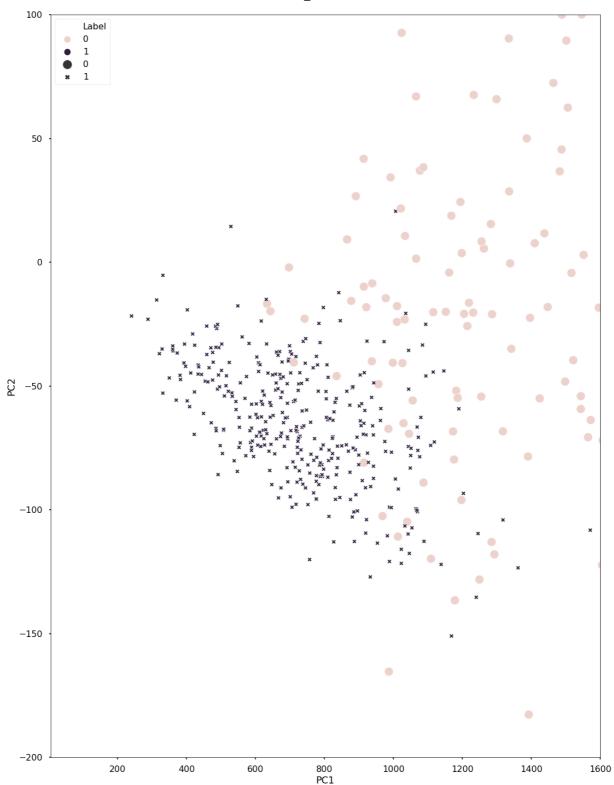

First impression gave me the look of overlapping of data values and for further analysis I'll go ahead with the first two components.

Positive patients are very tightly packed and yes there is some overlapping of both types of patients. One thing thats striking in my mind here is the close approximity of postive cases.

One more close look...

```
In [275... with plt.style.context('seaborn-poster'):
    plt.figure(figsize=(18,25))
    sns.scatterplot(data=cancer_transf,x='PC1',y='PC2',hue='Label',size=cancer_trans
    plt.xlim(right=1600)
    plt.ylim(bottom=-200,top=100)
```

Models_Performance
